Abstract In this work, we introduce a methodology to approximate unknown parameters that appear on a non-linear reaction–diffusion model of tumor invasion. These equations consider that tumor-induced alteration of micro-environmental pH furnishes a mechanism for cancer invasion. A coupled system reaction–diffusion explaining this model is given by three partial differential equations for the non-dimensional spatial distribution and temporal evolution of the density of normal tissue, the neoplastic tissue growth and the excess concentration of H^+ ions. The tumor model parameters have a corresponding biological meaning: the reabsorption rate, the destructive influence of H^+ ions in the healthy tissue, the growth rate of tumor tissue and the diffusion coefficient. We propose to solve the direct problem using the Finite Element Method (FEM) and minimize an appropriate functional including both the

1 Introduction

Cancer is one of the greatest killers in the world although medical activity has been successful, despite great difficulties, at least for some pathologies. A great effort of human and economical resources is devoted, with successful outputs, to cancer modeling (Cristini and Lowengrub 2010; Adam and Bellomo 1997; Bellomo et al. 2008a, b; Byrne 2010; Preziosi 2003).

Some comments on the importance of mathematical modeling in cancer can be found in the literature. In the work of Bellomo et al. (2008b) it is mentioned that “Cancer modelling has, over the years, grown immensely as one of the challenging topics involving applied mathematicians working with researchers active in the biological sciences. The motivation is not only scientific as in the industrial nations cancer has now moved from seventh to second place in the league table of fatal diseases, being surpassed only by cardiovascular diseases”.

In this work, we use the mathematical analyses first proposed by Gatenby and Gawlinski (1996) which support the acid-mediated invasion hypothesis, hence it is acquiescent to mathematical representation as a reaction–diffusion system at the tissue scale, describing the spatial distribution and temporal development of tumor tissue, normal tissue, and excess H^+ ion concentration.

The model predicts a pH gradient extending from the tumor–host interface. The effect of biological parameters critical to controlling this transition is supported by experimental and clinical observations (Martin and Jain 1994).

In the work by Gatenby and Gawlinski (1996), a model tumor invasion was introduced in an attempt to find a common, underlying mechanism by which primary and metastatic cancers invade and destroy normal tissues. This work is not attempting to model the large-scale morphological features of tumors such as central necrosis or modeling the genetic changes which result in transformation or seeking to understand the causes of these changes. Rather, it concentrates on the microscopic-scale population interactions occurring at the tumor–host interface, reasoning that these processes strongly influence the clinically significant manifestations of invasive cancer. Specifically, this work hypothesizes that the metabolism of the neoplastic tissue increased acid production and the diffusion of that acid into surrounding healthy tissue creates a microenvironment where tumor cells survive and proliferate whereas normal cells are unable to remain viable. The progressive loss of layers of normal cells at the tumor–host interface facilitates tumor invasion. Key elements of this tumor invasion mechanism are low interstitial pH of tumors due to primitive metabolism and reduced viability of normal tissue in a pH environment favorable to tumor tissue.

These model equations depend only on a small number of cellular and subcellular parameters. Analysis of the equations shows that the model predicts a crossover from a benign tumor to one that is aggressively invasive as a dimensionless combination of the parameters increases through a critical value.

Fig. 1 A micrographs of the tumor–host interface from human squamous cell carcinomas of the head and neck (Gatenby and Gawlinski 1996)

The dynamics and structure of the tumor–host interface in invasive cancers are shown to be controlled by the same biological parameters which generate the transformation from benign to malignant growth. A hypocellular interstitial gap, as we can see in Fig. 1 (Gatenby and Gawlinski 1996, Figure 4a), at the interface is predicted to occur in some cancers.

In the study by Quiroga et al. (2015), we develop an algorithm that allows us to estimate a unique parameter for a similar tumor model with a two-dimensional spatial variable. Here, we are interested in obtaining approximations for a pair of parameters that are related to the therapeutics, so we shall consider a one-dimensional spatial variable in the tumor model.

In this paper, we estimate a pair of parameters (the destructive influence of H^+ ions in the healthy tissue and the control in the buffer process of H^+ ions concentration) using an inverse problem. Moreover, via fluorescence ratio imaging microscopy, it is possible get data about the concentration of hydrogen ions (Martin and Jain 1994). We propose a framework via a PDE-constrained optimization problem, following the PDE-based model by Gatenby and Gawlinski (1996). In this approach, tumor invasion is modeled via a coupled nonlinear system of partial differential equations, which makes the numerical solution procedure quite challenging.

This problem is a particular application of the inverse problems which are used in applied sciences: structured population dynamics (Perthame and Zubelli 2007), computerized tomography and image reconstruction in medical imaging (van den Doel et al. 2011; Zubelli et al. 2003), and more specifically tumor growth (Agnelli et al. 2011; Hogeia et al. 2008; Knopoff et al. 2013), among many others.

We solve a minimization problem using a gradient-based method considering the adjoint method to find the derivative of an objective functional. In this way, we would obtain the best parameters that fit patient-specific data.

The contents of this paper is organized into seven sections as follows: Sect. 1 consists in some preliminaries about the model and the definition of the direct problem. Section 2 deals with the variational formulation of the direct problem. Section 3 considers the formulation of the minimization problem and the reduced and adjoint problem, deriving the optimality conditions for the problem. Section 4 finds the gradient of the functional with respect to

parameters that does not appear explicitly in the equation. Section 5 deals with the numerical solution of the adjoint problem, designing a suitable algorithm to solve it. In particular, we use the Finite Element Method. In Sect. 6, we show some numerical simulations to give information on the behavior of the functional and its dependence on the parameters including the corresponding tables. Section 7 presents the conclusions and some future work related to the contents of this paper.

2 Non-linear reaction–diffusion model of tumor invasion

We consider the mathematical model based on the theory of the change of the pH of the environment, proposed by [Gatenby and Gawlinski \(1996\)](#):

$$\frac{\partial N_1}{\partial t} = r_1 N_1 \left(1 - \frac{N_1}{K_1} \right) - d_1 L N_1, \quad (1)$$

$$\frac{\partial N_2}{\partial t} = r_2 N_2 \left(1 - \frac{N_2}{K_2} \right) + \nabla \cdot \left(D_{N_2} \left(1 - \frac{N_1}{K_1} \right) \nabla N_2 \right), \quad (2)$$

$$\frac{\partial L}{\partial t} = r_3 N_2 - d_3 L + D_{N_3} \Delta L, \quad (3)$$

which determines the spatial and temporal distribution of three variables: $N_1(x, t)$, the density of normal tissue; $N_2(x, t)$, the density of neoplastic tissue; and $L(x, t)$, the excess concentration of H^+ ions. The units of N_1 and N_2 are cells/cm³ and excess H^+ ion concentration is expressed as a molarity (M), x and t are the position (in cm) and time (in seconds), respectively.

In Eq. (1), the behavior of the healthy tissue is determined by the logistic growth of N_1 with growth rate r_1 and carrying capacity K_1 , and the interaction of N_1 with excess H^+ ions leading to a death rate proportional to L . The number $d_1 L$ is the excess acid concentration, dependent death rate in accord with the well-described decline in the growth rate of normal cells, due to the reduction of pH from its optimal value of 7.4. The constants r_1 , d_1 and K_1 have units of 1/s, l/(M s) and cells/cm³, respectively.

For Eq. (2), the neoplastic tissue growth is described by a reaction–diffusion equation. The reaction term is governed by a logistic growth of N_2 with growth rate r_2 and carrying capacity K_2 . The diffusion term depends on the absence of healthy tissue with a diffusion constant D_{N_2} . Constants r_2 , K_2 and D_{N_2} have units of 1/s, cells/cm³ and cm²/s, respectively.

In Eq. (3), it is assumed that excess H^+ ions are produced at a rate proportional to the neoplastic cell density, and diffuse chemically. An uptake term is included to take into account the mechanisms for increasing local pH (e.g., buffering and large-scale vascular evacuation; [Gatenby and Gawlinski 1996](#)). Constant r_3 is the production rate [M cm³/(cell s)], d_3 is the reabsorption rate (1/s), and D_{N_3} is the H^+ ion diffusion constant (cm²/s).

All the parameter values can be found in Table 1.

2.1 Nondimensionalization

Following the ideas exposed in [Gatenby and Gawlinski \(1996\)](#), and considering one-dimensional space variables, the mathematical model is rescaled and the spatial and temporal domains are transformed onto the intervals $I = (0, 1)$ and $[0, T]$, respectively. Hence, let us define the following change of variables:

Table 1 Parameter values used in Gatenby and Gawlinski (1996)

Parameter	Estimate
K_1	$5 \times 10^7/\text{cm}^3$
K_2	$5 \times 10^7/\text{cm}^3$
r_1	$1 \times 10^{-6}/\text{s}$
r_2	$1 \times 10^{-6}/\text{s}$
D_{N_2}	$2 \times 10^{-10} \text{ cm}^2/\text{s}$
D_{N_3}	$5 \times 10^{-6} \text{ cm}^2/\text{s}$
r_3	$2.2 \times 10^{-17} \text{ M cm}^3/\text{s}$
d_3	$1.1 \times 10^{-4}/\text{s}$

$$\begin{aligned}
 u_1 &= \frac{N_1}{K_1} & u_2 &= \frac{N_2}{K_2} & u_3 &= \frac{L}{L_0} \\
 \tau &= r_1 t & \xi &= \sqrt{\frac{r_1}{D_{N_3}}} x
 \end{aligned}
 \tag{4}$$

where $L_0 = r_3 K_2 / d_3$. We will continue denoting x and t instead of ξ and τ , respectively. Using the transformation (4) the dimensionless form of the Eqs. (1)–(3) becomes

$$\frac{\partial u_1}{\partial t} = u_1(1 - u_1) - \delta_1 u_1 u_3,
 \tag{5}$$

$$\frac{\partial u_2}{\partial t} = \rho_2 u_2(1 - u_2) + \frac{\partial}{\partial x} \left(D_2(1 - u_1) \frac{\partial u_2}{\partial x} \right),
 \tag{6}$$

$$\frac{\partial u_3}{\partial t} = \delta_3(u_2 - u_3) + \frac{\partial^2 u_3}{\partial x^2},
 \tag{7}$$

for $(x, t) \in I \times (0, T]$, where the four dimensionless quantities which parameterize the model are given by:

$$\delta_1 = \frac{d_1 r_3 K_2}{d_3 r_1}, \quad \rho_2 = \frac{r_2}{r_1}, \quad D_2 = \frac{D_{N_2}}{D_{N_3}}, \quad \delta_3 = \frac{d_3}{r_1}.$$

The interaction parameters between different cells (healthy and tumor) and concentration of H^+ are difficult to measure experimentally. This is the reason for which we propose to estimate δ_1 . Also we will focus on δ_3 because we are interested in the buffering process that will allow to initiate the study of the therapeutic of this problem. The other parameters can be estimated by different techniques (see Table 1).

2.2 Initial and boundary conditions

At $t = 0$ we will consider the tumor at a certain stage of its evolution. Hence, the initial conditions are:

$$u_i(x, 0) = u_i^0(x), \quad i = 1, 2, 3,
 \tag{8}$$

for all $x \in [0, 1]$. We assume that the tumor is on the left of the domain, in the sense that the tumor cells are not moving. Then, for all $t \in (0, T]$, we have

$$\frac{\partial u_1}{\partial x}(0, t) = 0, \quad u_1(1, t) = 1,
 \tag{9}$$

$$\frac{\partial u_2}{\partial x}(0, t) = 0, \quad u_2(1, t) = 0, \tag{10}$$

$$\frac{\partial u_3}{\partial x}(0, t) = 0, \quad u_3(1, t) = 0. \tag{11}$$

From now on, Eqs. (5)–(11) will be referred to as the direct problem.

2.3 Weak formulation of the direct problem

In this subsection, we use $\langle \cdot, \cdot \rangle$ to denote the duality pairing, i.e., $\langle \cdot, \cdot \rangle : U^* \times U \mapsto \mathbb{R}$ such that $\langle w, u \rangle = w(u)$ (the space is always clear from the context), we emphasize that U^* is the space of continuous linear functionals over U .

Using the variational techniques for obtaining the weak solution of the direct problem (Ladyzhenskaya et al. 1988; Kinderlehrer and Stampacchia 2000; Evans 1998), we can write the weak formulation of (5)–(11) as $E(u, \omega) = 0$, where $E : U \times \mathbb{R}^2 \mapsto U^* \times (L^2(I))^3$ such that

$$\begin{aligned} \langle E(u, \omega), \zeta \rangle &= \int_{I_T} \left(\frac{\partial u_1}{\partial t} \lambda_1 - (1 - \tilde{u}_1 - u_1 - \delta_1 u_3)(\tilde{u}_1 + u_1) \lambda_1 \right) \\ &+ \int_{I_T} \left(\frac{\partial u_2}{\partial t} \lambda_2 - \rho_2 u_2 (1 - u_2) \lambda_2 + D_2 (1 - \tilde{u}_1 - u_1) \frac{\partial u_2}{\partial x} \frac{\partial \lambda_2}{\partial x} \right) \\ &+ \int_{I_T} \left(\frac{\partial u_3}{\partial t} \lambda_3 + \delta_3 (u_3 - u_2) \lambda_3 + \frac{\partial u_3}{\partial x} \frac{\partial \lambda_3}{\partial x} \right) \\ &+ \int_0^1 (\tilde{u}_1(0) + u_1(0) - u_1^0) \gamma_1 + \int_0^1 (u_2(0) - u_2^0) \gamma_2 \\ &+ \int_0^1 (u_3(0) - u_3^0) \gamma_3 \\ &= \left\langle \frac{\partial u}{\partial t} + F(u), \lambda \right\rangle + \langle u(0) - u^0, \gamma \rangle, \end{aligned} \tag{12}$$

where $I_T = I \times [0, T]$, $u = (u_1, u_2, u_3) \in U$, $\tilde{u}(x, t) = \tilde{v}(x)$ with $\tilde{v} \in (H^1(I))^3$ and $\tilde{v}(1) = (1, 0, 0)$ is the Dirichlet lift, $\omega = (\delta_1, \delta_3) \in \mathbb{R}^2$, $\zeta = (\lambda, \gamma)$ with $\lambda = (\lambda_1, \lambda_2, \lambda_3) \in U$, $\gamma = (\gamma_1, \gamma_2, \gamma_3) \in (L^2(I))^3$,

$$\begin{aligned} U &= \left\{ u \in L^2(0, T; V) \mid \frac{\partial u}{\partial t} \in L^2(0, T; V^*) \right\}, \\ L^2(0, T; V) &= \left\{ u : (0, T) \mapsto V \mid \int_0^T \|u(t)\|_{(H^1(I))^3}^2 < +\infty \right\}, \end{aligned}$$

with $V = \{v \in (H^1(I))^3 \mid v(1) = 0 \in \mathbb{R}^3\}$, and $H^1(I)$ and $L^2(I)$ are the standard Sobolev and Lebesgue function spaces, respectively. In summary, for u such that $E(u, \omega) = 0$ we obtain that $\tilde{u} + u$ is a weak solution of the direct problem.

3 The minimization problem

Suppose that in a time interval $0 \leq t \leq T$ experimental information is available and that given a choice of ω we represent by u the solution of the direct problem. Then, we propose to estimate δ_1 and δ_3 by solving the following inverse problem:

Given available information over the time window $0 \leq t \leq T$, find a parameter ω able to generate data u that best match the given data.

First of all, we have to check which variables are observable, that is, which variables can be experimentally measured. [Martin and Jain \(1994\)](#) and [Gatenby et al. \(2006\)](#) proposed to measure the excess concentration of H^+ ions at certain times $t_k, k = 1, \dots, M$ using fluorescence ratio imaging microscopy. We assume that we have observations of the dimensionless variable u_3 that correspond to the variable L (the excess concentration of H^+ ions).

We define a distance (depending on the parameter ω) between the experimental data and the solution of the PDE system generated using ω as a parameter. This distance is in fact an objective functional to be minimized. So, the functional $J : U \times \mathbb{R}^2 \mapsto \mathbb{R}$ could be defined as:

$$J(u, \omega) = \frac{1}{2} \int_0^T \int_0^1 [u_3(x, t) - \hat{u}_3(x, t)]^2 \chi(t) dx dt, \tag{13}$$

where

$$\chi(t) = \sum_{k=1}^M e^{(-C(t-t_k)^2)},$$

is a weight function with C large enough, $\hat{u}_3(x, t)$ is the excess concentration measured experimentally and $u_3(x, t)$ is the excess concentration of H^+ ions obtained by solving the direct problem for a certain choice of ω .

Thus, we are interested in finding a solution of the PDE-constrained minimization problem

$$\begin{aligned} & \underset{(u, \omega) \in U \times \mathbb{R}^2}{\text{minimize}} && J(u, \omega) \\ & \text{subject to} && E(u, \omega) = 0, \\ & && \omega \in \Omega_{\text{ad}}, \end{aligned} \tag{14}$$

where Ω_{ad} is the set of admissible values for ω . In our case, we can choose $\Omega_{\text{ad}} = (0, \infty) \times (0, \infty)$. Notice that the constraint $E(u, \omega) = 0$ constitutes the direct problem.

There is a fundamental difference between the direct and inverse problem. Usually, inverse problems are ill posed in the sense of existence, uniqueness and stability of the solution. Thus, regularization techniques can be considered ([van den Doel et al. 2011](#); [Engl et al. 1996](#); [Kirsch 2011](#)).

3.1 The adjoint method

In the following, for a function $F : U \times D \mapsto Z$ such that $(u, \delta) \mapsto F(u, \delta)$, we denote by $F'(u, \delta)$ the full Fréchet-derivative and by $\frac{\partial F}{\partial u}(u, \delta)$ and $\frac{\partial F}{\partial \delta}(u, \delta)$ the partial Fréchet derivatives of F at (u, δ) . For a linear operator $T : V \mapsto Z$ we denote by $T^* : Z^* \mapsto V^*$ the adjoint operator of T .

We will consider the so-called reduced problem:

$$\begin{aligned} & \underset{\omega \in \mathbb{R}^2}{\text{minimize}} && \tilde{J}(\omega) = J(S(\omega), \omega) \\ & \text{subject to} && \omega \in \Omega_{\text{ad}}, \end{aligned} \tag{15}$$

where $\tilde{J} : \mathbb{R}^2 \mapsto \mathbb{R}$ and $S : \Omega_{\text{ad}} \mapsto U$ is given as the solution of $E(S(\omega), \omega) = 0$. The existence of the function S is obtained by the implicit function theorem. According to the ideas exposed by [Brandenburg et al. \(2009\)](#), [Hinze \(2009\)](#), this can be done since E is a continuously Fréchet-differentiable function, and assuming that for each $\omega \in \Omega_{\text{ad}}$ there

exists a unique corresponding solution $u = S(\omega)$ such that the derivative $\frac{\partial E}{\partial u}(S(\omega), \omega)$ is a continuous linear operator continuously invertible. In addition, the solution of the problem (15) can be obtained by assuming that Ω_{ad} is a compact set and J is a continuous function.

To find a minimum of the continuously differentiable function \tilde{J} , it will be important to compute the derivative of this reduced objective function. Hence, we will show a procedure to obtain \tilde{J}' using the adjoint approach.

Since $E(S(\omega), \omega) = 0$, we have that $\tilde{J}(\omega) = J(S(\omega), \omega) + \langle E(S(\omega), \omega), \zeta \rangle$. Thus,

$$\begin{aligned} \tilde{J}'(\omega) &= (S'(\omega))^* \left(\frac{\partial J}{\partial u}(S(\omega), \omega) + \left(\frac{\partial E}{\partial u}(S(\omega), \omega) \right)^* \zeta \right) \\ &\quad + \frac{\partial J}{\partial \omega}(S(\omega), \omega) + \left(\frac{\partial E}{\partial \omega}(S(\omega), \omega) \right)^* \zeta. \end{aligned}$$

For a given ω , let us consider $\zeta_\omega \in U \times (L^2(I))^3$ as the solution of the so-called adjoint problem:

$$\frac{\partial J}{\partial u}(S(\omega), \omega) + \left(\frac{\partial E}{\partial u}(S(\omega), \omega) \right)^* \zeta_\omega = 0. \tag{16}$$

Note that each term in (16) is an element of the space U^* . Therefore, for $u_\omega = S(\omega)$ we obtain that

$$\tilde{J}'(\omega) = \frac{\partial J}{\partial \omega}(u_\omega, \omega) + \left(\frac{\partial E}{\partial \omega}(u_\omega, \omega) \right)^* \zeta_\omega, \tag{17}$$

where u_ω and ζ_ω are solutions of the direct and adjoint problem, respectively.

Notice that to obtain $\tilde{J}'(\omega)$ we need first to compute u_ω by solving the direct problem, followed by the calculation of ζ_ω by solving the adjoint problem. For computing the second term of (17) it is not necessary to obtain the adjoint of $\frac{\partial E}{\partial \omega}(u, \omega)$ but just its action over ζ .

4 Getting the derivative of the functional

To obtain the adjoint operator of $\frac{\partial E}{\partial u}(u, \omega) : U \mapsto U^* \times (L^2(I))^3$, recall that

$$\left\langle \left(\frac{\partial E}{\partial u}(u, \omega) \right)^* \zeta, \eta \right\rangle = \left\langle \frac{\partial E}{\partial u}(u, \omega)\eta, \zeta \right\rangle,$$

for any $\eta \in U$ and $\zeta \in U \times (L^2(I))^3$. Since

$$\left\langle \frac{\partial E}{\partial u}(u, \omega)\eta, \zeta \right\rangle = \lim_{\mu \rightarrow 0} \frac{\langle E(u + \mu\eta, \omega), \zeta \rangle - \langle E(u, \omega), \zeta \rangle}{\mu},$$

after some algebraics, it can be shown that

$$\begin{aligned} &\left\langle \frac{\partial E}{\partial u}(u, \omega)\eta, \zeta \right\rangle \\ &= \int_{I_T} \left(\frac{\partial \eta_1}{\partial t} - (1 - 2(\tilde{u}_1 + u_1) - \delta_1 u_3)\eta_1 + \delta_1(\tilde{u}_1 + u_1)\eta_3 \right) \lambda_1 \\ &\quad + \int_{I_T} \left(\frac{\partial \eta_2}{\partial t} - \rho_2(1 - 2u_2)\eta_2 \right) \lambda_2 + \int_{I_T} D_2 \left(-\frac{\partial u_2}{\partial x} \eta_1 + (1 - \tilde{u}_1 - u_1) \frac{\partial \eta_2}{\partial x} \right) \frac{\partial \lambda_2}{\partial x} \\ &\quad + \int_{I_T} \left(\frac{\partial \eta_3}{\partial t} - \delta_3(\eta_2 - \eta_3) \right) \lambda_3 + \int_{I_T} \frac{\partial \eta_3}{\partial x} \frac{\partial \lambda_3}{\partial x} + \int_0^1 (\eta_1(0)\gamma_1 + \eta_2(0)\gamma_2 + \eta_3(0)\gamma_3). \end{aligned}$$

Using integration by parts for time, we obtain

$$\begin{aligned} \left\langle \left(\frac{\partial E}{\partial u}(u, \omega) \right)^* \zeta, \eta \right\rangle &= \int_{I_T} \left(-\frac{\partial \lambda_1}{\partial t} - (1 - 2(\tilde{u}_1 + u_1) - \delta_1 u_3) \lambda_1 - D_2 \frac{\partial u_2}{\partial x} \frac{\partial \lambda_2}{\partial x} \right) \eta_1 \\ &\quad + \int_{I_T} \left(-\frac{\partial \lambda_2}{\partial t} - \rho_2(1 - 2u_2) \lambda_2 - \delta_3 \lambda_3 \right) \eta_2 \\ &\quad + \int_{I_T} D_2(1 - \tilde{u}_1 - u_1) \frac{\partial \lambda_2}{\partial x} \frac{\partial \eta_2}{\partial x} \\ &\quad + \int_{I_T} \left(-\frac{\partial \lambda_3}{\partial t} + \delta_1(\tilde{u}_1 + u_1) \lambda_1 + \delta_3 \lambda_3 \right) \eta_3 + \int_{I_T} \frac{\partial \lambda_3}{\partial x} \frac{\partial \eta_3}{\partial x} \\ &\quad + \int_0^1 \left(\lambda_1(T) \eta_1(T) + (\gamma_1 - \lambda_1(0)) \eta_1(0) \right) \\ &\quad + \int_0^1 \left(\lambda_2(T) \eta_2(T) + (\gamma_2 - \lambda_2(0)) \eta_2(0) \right) \\ &\quad + \int_0^1 \left(\lambda_3(T) \eta_3(T) + (\gamma_3 - \lambda_3(0)) \eta_3(0) \right). \end{aligned}$$

On the other hand,

$$\left\langle \frac{\partial J}{\partial u}(u, \omega), \eta \right\rangle = \int_0^T \int_0^1 (u_3(x, t) - \hat{u}_3(x, t)) \eta_3(x, t) \chi(t) dx dt.$$

Since $\frac{\partial J}{\partial u}(u, \omega) + \left(\frac{\partial E}{\partial u}(u, \omega) \right)^* \zeta = 0$ if and only if $\left\langle \frac{\partial J}{\partial u}(u, \omega) + \left(\frac{\partial E}{\partial u}(u, \omega) \right)^* \zeta, \eta \right\rangle = 0$ for all $\eta \in U$, we conclude that $\zeta = (\lambda, \gamma)$ satisfies $\frac{\partial J}{\partial u}(u, \omega) + \left(\frac{\partial E}{\partial u}(u, \omega) \right)^* \zeta = 0$ if and only if $\gamma = \lambda(0)$, $\lambda(T) = 0$ with $\lambda \in U$ satisfying

$$\begin{aligned} 0 &= \int_{I_T} \left(-\frac{\partial \lambda_1}{\partial t} - (1 - 2(\tilde{u}_1 + u_1) - \delta_1 u_3) \lambda_1 - D_2 \frac{\partial u_2}{\partial x} \frac{\partial \lambda_2}{\partial x} \right) \eta_1 \\ &\quad + \int_{I_T} \left(-\frac{\partial \lambda_2}{\partial t} - \rho_2(1 - 2u_2) \lambda_2 - \delta_3 \lambda_3 \right) \eta_2 \\ &\quad + \int_{I_T} D_2(1 - \tilde{u}_1 - u_1) \frac{\partial \lambda_2}{\partial x} \frac{\partial \eta_2}{\partial x} \\ &\quad + \int_{I_T} \left(-\frac{\partial \lambda_3}{\partial t} + \delta_1(\tilde{u}_1 + u_1) \lambda_1 + \delta_3 \lambda_3 + (u_3 - \hat{u}_3) \chi \right) \eta_3 \\ &\quad + \int_{I_T} \frac{\partial \lambda_3}{\partial x} \frac{\partial \eta_3}{\partial x} \\ &= \left\langle -\frac{\partial \lambda}{\partial t} + H(\lambda), \eta \right\rangle, \end{aligned} \tag{18}$$

for all $\eta \in U$. Thus, the weak formulation (18) shall be solved to get ζ_ω . Notice that the adjoint equations are posed backwards in time, with a final condition at $t = T$, while the state equations are posed forward in time, with an initial condition at $t = 0$.

Now, to compute the adjoint operator of $\frac{\partial E}{\partial \omega}(u, \omega) : \mathbb{R}^2 \mapsto U^* \times (L^2(I))^3$, for any $q = (q_1, q_3) \in \mathbb{R}^2$ and $\zeta \in U \times (L^2(I))^3$, we have

$$\begin{aligned} \left\langle \left(\frac{\partial E}{\partial \omega}(u, \omega) \right)^* \zeta, q \right\rangle &= \left\langle \frac{\partial E}{\partial \omega}(u, \omega)q, \zeta \right\rangle \\ &= \lim_{\mu \rightarrow 0} \frac{\langle E(u, \omega + \mu q), \zeta \rangle - \langle E(u, \omega), \zeta \rangle}{\mu} \\ &= \int_{I_T} (\tilde{u}_1 + u_1)u_3\lambda_1q_1 + \int_{I_T} (u_3 - u_2)\lambda_3q_3. \end{aligned}$$

On the other hand, since $\frac{\partial J}{\partial \omega}(u, \omega) = 0$, we obtain the following expression for (17),

$$\tilde{J}'(\omega) = \left(\frac{\partial E}{\partial \omega}(u_\omega, \omega) \right)^* \zeta_\omega = \begin{bmatrix} \int_{I_T} (\tilde{u}_1 + u_1)u_3\lambda_1 \\ \int_{I_T} (u_3 - u_2)\lambda_3 \end{bmatrix}. \tag{19}$$

5 Algorithms for the direct and inverse problem

The minimization of the objective functional \tilde{J} (which solution are the model parameters) is an iterative procedure that needs the derivative of the objective functional. Solving two PDE problems (the direct and adjoint problems) per iteration we can obtain \tilde{J}' , which is cheaper than solving the direct problem many times per iteration to get the derivative (Hinze 2009). We have implemented the algorithms in MATLAB, using the Finite Element Method for solving the direct and adjoint problems, and the Sequential Quadratic Programming (SQP) method for solving the optimization problem using the built-in function `fmincon`. At time

Fig. 2 Density of health and tumor cells, and excess concentration of H^+ ions at fixed time ($t = 20$) with respect to x variable, for $\delta_1 = 12.5$ and $\delta_3 = 70$

$t = 20$ and in terms of x variable, Fig. 2 shows excess concentration of H^+ ions, density of health cells and density of tumor cells.

In gradient-based optimization methods, we need to have the derivative of the objective function (Nocedal and Wright 2006). The solution of the adjoint problem (once per iteration) allows to get the derivative regardless the number of inversion variables. Notice that the direct and adjoint problems can be solved by the Finite Element Method.

Below we present the procedure to minimize the functional \tilde{J} .

Algorithm 51 Adjoint-based minimization method

1. Give an initial guess ω^0 for the parameter.
 2. In step k , given ω^k , solve the direct and adjoint problems.
 3. Get the derivative of the functional, i.e., $\tilde{J}'(\omega^k)$, using (19).
 4. Obtain ω^{k+1} by performing one iteration of the SQP method.
 5. Stop using the criteria of `fmincon`.
-

To perform the minimization procedure, it is necessary to solve both the direct problem and the adjoint problem.

Algorithm 52 Direct problem

1. Perform an implicit Euler step to find the state variables u , that is:

$$\frac{u(\cdot, t_n) - u(\cdot, t_{n-1})}{\tau} = F(u(\cdot, t_n)),$$

where $t_n = t_{n-1} + \tau$, $F(u(\cdot, t_n))$ is a nonlinear functional and the initial condition is $u^0(x) = u(x, 0)$.

2. Use FEM to make a discretization of $u_i(x, t_n)$:

$$u_i(x, t_n) \approx \sum_{j=1}^{nod} u_{i,j}^n \phi_j(x), \quad i = 1, 2, 3,$$

where ϕ_j are the linear shape functions and nod is the number of uniform distributed nodes for the spatial meshgrid for $[0, 1]$.

3. Calling $U^n = [U_1^n, U_2^n, U_3^n] \in \mathbb{R}^q$, where

$$U_i^n = [u_{i,1}^n, \dots, u_{i,j}^n, \dots, u_{i,nod}^n] \in \mathbb{R}^{nod}, \quad i = 1, 2, 3,$$

use the Newton method to find $U^n \in \mathbb{R}^q$ such as $U^n - U^{n-1} - \tau G(U^n) = 0$, where G is the discretization of F .

Algorithm 53 Adjoint problem

1. Perform an implicit Euler step to find the adjoint variable λ :

$$-\frac{\lambda(\cdot, t_n) - \lambda(\cdot, t_{n-1})}{\tau} = H(\lambda(\cdot, t_{n-1})),$$

where the final condition is $\lambda(\cdot, T) = 0$.

2. Use FEM to make a discretization of $\lambda(\cdot, t_n)$ and solve the linear problem

$$\lambda^{n-1} - \lambda^n - \tau K(\lambda^{n-1}) = 0,$$

where K is the discretization of H .

6 Computational results

In this section, we evaluate the performance of the adjoint-based optimization method proposed in this work. We show numerical simulations for some test cases using Algorithm 51.

Let us consider a synthetic experiment where $\hat{u}_3(x, t)$ is generated via the direct model, for a choice of the model parameters $\rho_2 = 1$, $D_2 = 4 \times 10^{-5}$ and $\hat{\omega} = (12.5, 70)$. We choose $\hat{\delta}_1 = 12.5$ with the objective of recovering the behavior of different cell densities as in Fig. 1.

The graph of (15) in terms of ω can be seen in Fig. 3, leaving constant the other parameters. Notice that \tilde{J} looks convex with respect to ω .

We want to test if we can retrieve the original value of the parameter. This is not an easy task since we do not know, for instance, if the optimization problem has a solution, or if that solution is unique, or if the optimization problem has multiple local minima.

We have run Algorithm 51 for several values of $\hat{\omega}$ where the initial condition ω^0 is randomly taken. Algorithms 52 and 53 were solved using the following algorithmic parameters: $\tau = 0.5$, $T = 20$, $\text{nod} = 201$ and $U_{\text{ad}} = [0, 20] \times [80, 120]$. Results can be seen in Table 2 where we can observe that the retrieved parameter is obtained very accurately since the standard deviation is small.

Since we have accurately retrieved the value of $\hat{\omega}$ for different initial values ω^0 , we will consider $\omega^0 = (8, 50)$ in the next experiment.

Fig. 3 The functional \tilde{J} for \hat{u}_3 generated with $\hat{\omega} = (12.5, 70)$

Table 2 Experiments for randomly initial data ω^0 , $\hat{\omega} = (12.5, 70)$, where S is the standard deviation and e_{δ_i} is the relative error

	$\bar{\omega}$	S	e_{δ_i}
δ_1	12.4749	1.5194	6.6878^{-3}
δ_3	69.9732	4.9359^{-2}	3.7610^{-4}

Table 3 Experiments for $\hat{\omega} = (12.5, 70)$ and $\sigma = 0.05$, where S is the standard deviation and e_{δ_i} is the relative error

	$\bar{\omega}$	S	e_{δ_i}
δ_1	13.2226	2.2095	1.7215^{-2}
δ_3	70.1958	8.5686^{-1}	2.7577^{-3}

Table 4 Experiments for $\hat{\omega} = (12.5, 70)$ and $\sigma = 0.08$, where S is the standard deviation and e_{δ_i} is the relative error

	$\bar{\omega}$	S	e_{δ_i}
δ_1	11.2916	2.8904	9.9735^{-3}
δ_3	69.8592	3.3723^{-1}	1.9819^{-3}

Table 5 Experiments for $\hat{\omega} = (12.5, 70)$ and $\sigma = 0.10$, where S is the standard deviation and e_{δ_i} is the relative error

	$\bar{\omega}$	S	e_{δ_i}
δ_1	11.7134	1.6167	4.0346^{-3}
δ_3	69.9574	7.8445^{-2}	5.9917^{-4}

Table 6 Experiments for $\hat{\omega} = (12.5, 70)$ and $\sigma = 0.15$, where S is the standard deviation and e_{δ_i} is the relative error

	$\bar{\omega}$	S	e_{δ_i}
δ_1	10.1207	3.2747	2.6460^{-2}
δ_3	69.6646	5.1785^{-1}	4.7218^{-3}

The presence of noise in the data (due for example to measurement errors) may imply strong numerical instabilities in the solution of an inverse problem (Bertero and Piana 2006). One of the techniques to obtain values of \hat{u}_3 is by fluorescence ratio imaging microscopy (Martin and Jain 1994). Measurement errors can be seen as random perturbations in the data.

Therefore, we can assume that we have observations of \hat{u}_3 affected by Gaussian random noise with zero mean and standard deviation $\sigma = 0.01, 0.05, 0.08, 0.1, 0.15$. In Tables 3, 4, 5, 6 we show, for each σ , the average $\bar{\omega}$ over 10 values of ω , the standard deviation S and the relative error for each parameters $e_{\delta_i} = \frac{|\hat{\delta}_i - \bar{\delta}_i|}{\bar{\delta}_i}, i = 1, 3$.

7 Conclusions

A miscellany of new strategies, experimental techniques and theoretical approaches are emerging in the ongoing battle against cancer. Nevertheless, as new, ground-breaking discoveries relating to many and diverse areas of cancer modeling are made, scientists often have recourse to mathematical modeling to elucidate and interpret these experimental findings (Adam and Bellomo 1997; Bellomo et al. 2008b; Byrne 2010; Araujo and McElwain 2004), and it became clear that these models are expected to success if the parameters involved in the modeling process are known. Or eventually, taking into account that some biological parameters may be unknown (especially in-vivo), the model can be used to obtain them (Agnelli et al. 2011; van den Doel et al. 2011).

This paper, as already mentioned in Sect. 1, aims to offer a mathematical tool for the obtention of phenomenological parameters δ_1 and δ_3 representing the negative influence of

the protons ions in the tissue (the acidification of the environment where the cells live) and the buffering (the way that the body naturally eliminates the exceeding of protons ions), respectively. These parameters can be identified by inverse estimation, by making suitable comparisons with experimental data. The inverse problem was stated as a PDE-constrained optimization problem, which was solved using the adjoint method. In addition, the gradient of the proposed functional is obtained and can be extended, in principle, to any number of unknown parameters.

We remark that the parameter estimation via PDE-constrained optimization is a general approach that can be used, for instance, to consider the effects of nonlinear interaction between the health and tumor cells (McGillen et al. 2013), and the buffering coefficient that allow us in future to design a methodology to take into account the therapeutic of our problem.

As a future work, we are interested in the dependence of the δ_3 on time, as in Martin et al. (2010).
