Abstract

Four species of *Borreria* subsection *Latifoliae* (Rubiaceae) present intrafloral variations in the insertion/length of stamens in homostylous flowers. *Borreria heterantha* is described and illustrated as new species from the state of Pará, Brazil. The emended descriptions of *Borreria hispida*, *B. semiamplexicaule* and *B. xanthophylla*, with details on stamens morphology and insertion, are provided. The inclusion of *B. xanthophylla* in the subsection *Latifoliae* is proposed. Staminal arrangement, pollen grains and seed morphology of the four species are compared. A comparative table with ecological, palynological, and morphological features of each species is provided. In addition, *Borreria semiamplexicaule* is mentioned as a new record for the state of Mato Grosso, Brazil, and the lectotype of *B. hispida* is here designated.

Key words: *Borreria* subsect. *Latifoliae*, *Borreria heterantha*, *Borreria hispida*, *Borreria semiamplexicaule*, *Borreria xanthophylla*, Brazil, French Guiana, stamen organization, pollen grains, seed morphology, Spermacoce, Spermacoceae

Introduction

Borreria Meyer (1818: 79) belongs to tribe Spermacoceae, Rubiaceae. About 100 species of this Neotropical genus are distributed in the Americas, ranging from southern United States to southern Uruguay and central Argentina. Brazil is the country with the highest diversity, where ca. 77 species are found (Bacigalupo & Cabral 2007; Cabral & Salas 2013).

In the last decades, the taxonomic delimitation of *Borreria* and its relative *Spermacoce* Linnaeus (1753: 102) has been debated. This debate is due to morphological variation, incomplete understanding of the group, and divergent taxonomic views. Some authors consider the two taxa as separate genera based on morphological characters (Steyermark 1972; Bacigalupo & Cabral 1996, 2007; Bacigalupo *et al.* 2010; Cabral *et al.* 2010, 2011, 2012a, 2012b; Miguel & Cabral 2013; Salas *et al.* 2011). These authors circumscribe *Spermacoce* *s.str.* by having relatively small flowers arranged in pseudoaxillary glomerules, corolla lobes internally pilose, stamens sessile, style short, all included, and indehiscent capsules or capsules with only one dehiscent valve. These authors grouped ca. 10 American species with these features (Salas *et al.* unpubl. data) in the genus *Spermacoce*. In contrast, they consider *Borreria* as possessing relatively large flowers [except species that belong to *Borreria* section *Pseudodiodia* Hassler (1915: 166–167), which are under study (Salas *et al.* unpubl. data)], arranged in axillary and spherical glomerules, corolla lobes mostly glabrous or glabrescent, stamens with well-developed filaments, style long and exserted, and dehiscent capsules with both mericarps dehiscing septicidally or with indehiscent mericarps. According to these authors, while *Spermacoce* *s.str.* has zonocolporate pollen grains with long ectocolpi surrounded by spinules and endoapertures forming an endocingulum (Type 1 *sensu* Pire 1996), *Borreria* has several pollen types and is an eurypalynous genus (Pire 1996). In contrast, other authors treated *Borreria* as synonymous with *Spermacoce* [In the Paleotropics: Verdcourt (1976), Sivarajan *et al.* (1987), Dessein (2003), Dessein *et al.* (2003a, 2003b) and Harwood & Dessein (2005); in the Neotropics: Adams in Burger & Taylor (1993), Adams & Taylor (2012) Delprete (2007, 2010), Delprete *et al.* (2005) and Delprete & Cortés (2006)].

Recent molecular phylogenetic studies are inconclusive with respect to well supported clade delimitations and morphology. For example, the most comprehensive studies (Kårehed *et al.* 2008, Groeninckx *et al.* 2009) found that

some species of the *Borreria-Spermacoce* complex appear intermingled among a few monophyletic and morphologically well-defined Spermacoceae genera [i.e., *Mitracarpus* Zuccarini (1827: 210), *Richardia* Linnaeus (1753: 330), and *Psyllocarpus* Martius & Zuccarini (1824: 130)]. These studies aimed at resolving phylogenetic relationships within certain clades, as the “*Oldenlandia-Hedyotis* group” (Groeninckx *et al.* 2009, Wikström *et al.* 2013), or finding support for the description of new genera, as *Amphistemon* Groeninckx (2010: 450) and *Thamnoldenlandia* Groeninckx (2010: 458) (Groeninckx *et al.* 2010). However, sampling within the American *Borreria-Spermacoce* group has been very limited. Due to this limitation and such incongruences, the two genera are here maintained separate, following the generic delimitations adopted by our research group (Cabral *et al.* 2011, 2012a; Miguel & Cabral 2013; Salas *et al.* 2011).

The species here treated have capsules with longitudinal dehiscence, stamens and style exserted, and a bifid stigma. These traits characterize *Borreria* subsection *Latifoliae* (Schumann 1888: 41) Bacigalupo & E.L.Cabral (1996: 306), which includes ca. 10 species of herbs, erect or scandent subshrubs.

As part of a revision of the South American species of *Borreria* subsection *Latifoliae*, here we evaluate several unidentified specimens that might belong to two undescribed species displaying a peculiar and unusual phenomenon scarcely documented in Spermacoceae, and even in Rubiaceae. These two species have homostylous flowers with staminal dimorphism. In one of them, the dimorphism is due to different filaments lengths, while in the other species the stamens are inserted at two different levels in the corolla tube. As a result of the analyses of these species, we concluded that one of them is *Borreria xanthophylla* Bremekamp (1934: 306), a species not previously included in this group. Moreover, we discovered this staminal variation in two additional species of this subsection: *B. hispida* Spruce ex Schumann (1888: 62) and *B. semiamplexicaule* E.L. Cabral (1996: 37). Interestingly, the insertion of the stamens at different levels of the corolla tube was described and illustrated for the first time in the *Latifoliae* group by Aublet (1775) in *Spermacoce alata* Aublet (1775: 60, pl. 22, fig. 2, = *Borreria alata* (Aublet) Candolle (1830: 544)). However, this trait was overlooked and barely used by subsequent authors (Lamarck & Poiret 1783; Widenow 1798; Cuvier 1827; Don 1834).

Based on these observations and additional features, we describe *Borreria heterantha* E.L. Cabral & Sobrado as a new species from the state of Pará, Brazil, transfer *B. xanthophylla* to *Borreria* subsection *Latifoliae*, and complement the descriptions of *B. hispida*, *B. semiamplexicaule* and *B. xanthophylla*. We compare the staminal arrangements, pollen grains and seed morphology of these species. In addition, we indicate *Borreria semiamplexicaule* as a new record for Mato Grosso, Brazil and designate the lectotype for *B. hispida*. Finally, we compare the four species in a table with ecological, palynological, and morphological features (Table 1).

TABLE 1. Comparison of ecological, palynological and morphological features of *Borreria heterantha*, *B. hispida*, *B. semiamplexicaule* and *B. xanthophylla*.

Features	<i>Borreria heterantha</i>	<i>Borreria hispida</i>	<i>Borreria semiamplexicaule</i>	<i>Borreria xanthophylla</i>
Ecology	<i>Campos rupestres</i> and gramineous flat fields on canga, and also in shrubby vegetation with iron outcrops.	Open grasslands, savannas and rocky fields or granitic outcrops, occasionally along roadsides.	Flooded grassy fields, <i>campos rupestres</i> on outcrop of ferrous rocks, transitions between low forests to ombrophilous dense forest, near water courses. Always associated with marsh and wetlands.	Edges of shrubby vegetation on rocks, bordering with rocky savanna.
Habit	(15–)20–50 cm tall (2–)4–5 opposite lateral branches	7–30 cm tall 4–5 opposite lateral branches	15–50 cm tall Stems simple or with opposite lateral branches starting from the base	15 cm tall (30–60 cm long) 3–5 opposite lateral branches
Vestiture	Glabrous	Glabrous with tiny papilla at the angle or densely hispid	Glabrous	Glabrous to hispid at the angles

Material and Methods

This study is based on recent collections, herbarium material from BHCB, BM, BR, CEN, CTES, HEPH, HUEFS, IAN, INPA, M, MBM, MG, MO, NY, P, R, RB, UB, and W (Thiers 2013), and images available on Jstor Plants (<http://plants.jstor.org>). We used conventional taxonomic methods for the external morphology analyses and descriptions. Distribution is based on herbaria materials. The conservation status was proposed following the recommendations of *IUCN Red List Categories and Criteria, Version 3.1* (IUCN 2012). GeoCAT (Bachman *et al.* 2011) was used for calculating the Extent of Occurrence (EOO) and the Area of Occurrence (AOO). The width of the grid followed the recommendations of IUCN (2012), being set at 2 km².

We described the pollen grain and seed morphology based on the following samples taken from herbarium material: ***Borreria heteranthera***: A. J. Arruda, P. L. Viana, F. M. Santos, P. B. Mayer; T. J. Battituci & L. J. Arruda 826 (BHCB, CTES)*; ***Borreria hispida***: R. Spruce (BM, R, NY, M, W), W. J. Burchell 8675 (BR)*, M. A. da Silva, R. C. Mendonça, N. G. Souza, N. R. Oliveira & E. Cardoso 4033 (NY), A. Gröger 986 (M); ***Borreria semiamplexicaule***: D. Daly, R. Callejas, M. G. da Silva, E. Taylor, C. Rosario & M. dos Santos 1993 (CTES), P. M. Burkowski, A. J. Arruda, P. L. Viana, F. M. Santos & T. J. Battituci 1187 (BHCB), P. L. Viana, F. S. Marino, A. J. Arruda, T. B. Jorge & P. M. Burkowski 5269 (BHCB, CTES), A. J. Arruda, F. M. Santos, L. J. Arruda & T. J. Battituci 928 (BHCB)*, A. J. Arruda, F. M. Santos, L. J. Arruda & T. J. Battituci 1003 (BHCB)*, A. J. Arruda, F. M. Santos, L. J. Arruda & T. J. Battituci 1095 (BHCB)*, P. L. Viana, F. S. Marino, A. J. Arruda, T. B. Jorge & P. M. Burkowski 5257 (BHCB)*; ***Borreria xanthophylla***: J. J. de Granville, F. Crozier & C. Sarthou 15017 (BR)*, R. Benoist 1507 (P). The specimens marked with an asterisk were also used for seed micromorphological analyses.

Pollen grains were acetolyzed according to Erdtman (1966) and mounted in glycerine jelly for analyses with a light microscope (LM). We measured the equatorial diameter (E), the polar axis (P), and the colpi and pori lengths in at least 20 grains under LM. To express the relative length of colpi we used the length colpi/polar axis rate multiplied by 100 (LC/P) (Dessein *et al.* 2002). All other measurements were made using scanning electron microscope (SEM) graphs. For SEM analyses, seeds and acetolyzed pollen grains were sputter-coated with gold, and then photographed with a Jeol 5800 LV SEM. Broken pollen grains were also observed with the SEM, to observe their internal morphology. Pollen terminology follows Punt *et al.* (2007) and seeds terminology follows Stearn (1986).

Results

Two zygomorphic staminal arrangements were observed in the species of *Borreria* here treated. These features are the first record observed in homostylous species of Spermacoceae, and until now only found in these four species of the *Borreria* subsection *Latifoliae*. The configurations of insertion/length of the stamens are constant in all the examples and flowers of each species analyzed. Also, the pollen grain morphology is uniform in all anthers of the flower buds analyzed, independently of the staminal arrangement. This probably indicates that the different length or insertion of the stamens do not affect the pollen production and viability.

Staminal arrangements:—In *Borreria heteranthera* and *B. semiamplexicaule* the four exserted stamens are inserted at the sinuses of the corolla lobes, and both taxa, while being homostylous present dimorphic filaments. *B. heteranthera* has two stamens with shorter filaments, and other two with longer filaments (Figs. 3 H, 4 C). While in *B. semiamplexicaule* the two shorter stamens have subsessile anthers (Figs. 6 I, 7 C–D). In contrast to this staminal arrangement, the other two species analyzed have stamens inserted at different levels in the corolla tube. In *Borreria hispida* two stamens are exserted and have longer filaments, while the other two are barely exserted and have shorter filaments (Fig. 5 F). In contrast, *B. xanthophylla* has two barely exserted stamens, and the other two are included and have subsessile anthers (Fig. 8 J). In the last two species, the stamens with shorter filaments are inserted in the corolla tube, while the stamens with longer filaments are inserted at the interlobular sinuses.

Pollen grain morphology:—In *Borreria heteranthera*, pollen grains are 9–10-zonocolpate, medium-sized ($P=40$ (42.3) 44 μm ; $E=40$ (42) 45 μm diam.), and oblate-spheroidal to prolate-spheroidal ($P/E=0.98$ (1) 1.04). The outline is circular in polar view. The ectoaperture is a medium-sized, slit-like colpus ($LC/P=30$ (32) 36). The endoaperture appears as a pore at SEM, whereas at LM analyses reveal that is an endocingulum; whose width is 2/3 the length of the ectocolpus, with 10 μm at the ectocolpus area. The tectum is perforate, uniformly spinulate, and 2–3 μm thick; the infratectum is columellar. The perforations are subcircular or irregular, small and intermingled with larger ones, 0.16–0.26 μm . The nanospines 0.25–0.3 μm long (Fig. 1 A–C).

In *Borreria hispida*, pollen grains are 8–9(–10)-zonocolpate, medium-sized ($P=29$ (33.94) 38 μm ; $E=33$ (35.91) 43 μm diam.), and oblate-spheroidal to prolate-spheroidal ($P/E=0.86$ (0.94) 1.06). The outline is circular in polar view. The ectoaperture is a medium-sized, slit-like colpus ($LC/P=26$ (32.78) 39). The endoaperture is similar to a pore when observed at LM, but in fact is an endocingulum; the width of the endoaperture is 2/3 of the length of the ectocolpus, with extensions at the mesocolpium, 7 (7.95) 10 μm long the ectocolpus area. The tectum is perforate, uniformly spinulate, and 2–2.5 μm thick; the infratectum is columellar. The perforations are subcircular and irregular, comma-like, 0.2–0.4 μm . The nanospines are 0.3–0.4 μm long. The inner nexine surface is finely granular with numerous broad and deep endocracks. (Figs. 1 D–F, 2 A–B).

In *Borreria semiamplexicaule*, pollen grains are 9–10(–11)-zonocolpate, medium-sized ($P=31$ (34.08) 39 μm ; $E=35$ (37.73) 40 μm diam.) and oblate-spheroidal ($P/E=0.86$ (0.90) 0.98). The outline is circular in polar view. The ectoaperture is a medium-sized, slit-like colpus ($LC/P=28$ (31.96) 38). The endoaperture is fused, forming an endocingulum; whose width is 2/3 the length of the ectocolpus, with 7 (8.43) 10 μm at the ectocolpus area. This was confirmed with LM analyses. The tectum is perforate, uniformly spinulate, and 2–3 μm thick; the infratectum is columellar. The perforations are subcircular to irregular, comma-like, 0.2–0.4 μm . The nanospines are 0.4–0.5 μm long. The inner nexine surface is very finely granular with superficial irregular endocracks (Figs. 1 G–I, 2 C).

In *Borreria xanthophylla*, pollen grains are 9–10-zonocolpate, medium-sized ($P=36$ (40.8) 45 μm ; $E=40$ (42.5) 45 μm diam.), and oblate-spheroidal ($P/E=0.84$ (0.91) 1). The outline is circular in polar view. The ectoaperture is a short, slit-like colpus ($LC/P=23$ (24.64) 27). The endoaperture is an endocingulum confirmed at LM; whose width is 1/3 the length of the ectocolpus, with 4 (4.2) 5 μm at the ectocolpus area. The tectum is perforate, uniformly spinulate, and 1.3–1.6 μm thick; the infratectum is columellar. The perforations are subcircular, 0.22–0.42 μm . The nanospines are 0.3–0.6 μm long. The inner nexine surface is finely granular. (Figs. 1 J–L, 2 D).

Taxonomy

***Borreria heteranthera* E.L. Cabral & Sobrado, sp nov.** (Figs. 1 A–C, 3 A–L, 4 A–C, 9 A–C)

Type:—BRAZIL, Pará, Canaã dos Carajás, S11A, 6°20'47" S, 50°25'52" W, 737 m, 25 April 2012, *A. J. Arruda, F. M. Santos, L. J. Arruda & T. J. Battituci* 1099 (holotype BHCB 158091!; isotype CTES!).

Borreria heteranthera is similar to *B. semiamplexicaule* in being an annual herb, with two pairs of unequal involucral bracts, and papillate seeds; the former differs from the latter in having non-sheathing bracts (vs. sheathing in *B. semiamplexicaule*), the external pair of bracts 9–40 (50) × 1–10 mm (vs. 8–27 × 2–3.5 mm), the internal pair of bracts 4–10 (12) × 0.5–3 mm (vs. 4.4–8 × 2–3.2 mm), and two long and two short filaments (vs. two long filaments and two subsessile anthers).

Annual erect herb, (15–)20–50 cm tall; stems with (2–)4–5 opposite lateral branches or rarely simple, subquadrangular at the base, quadrangular and winged in young growth, glabrous, internodes 4–8 cm long. Stipular sheaths 2–4 mm long, scabrid to puberulous; setae (4–)5, 1–4 mm long, glabrous and colleter-tipped. Leaves opposite, pseudo-petiolate; blades ovate to elliptic, 25–50(–70) × 8–10(–20) mm, attenuate at base, acute at apex, membranaceous, glabrous above, puberulous or scabrid underneath, margin scaberulous, main nerve weakly marked; secondary veins inconspicuous. Inflorescences with 1 terminal and 1–2(–3) axillary glomerules, on principal stems and opposite lateral branches, pauciflorous; bracts 4, unequal, not sheathing, the larger and external pair of bracts 9–40(–50) × 1–10 mm, the smaller and internal pair of bracts 4–10(–12) × 0.5–3 mm. Flowers 4-merous, subsessile (pedicels 0.4–0.5 mm long). Hypanthium obpiriform, 1–1.5 mm long, scabrous. Calyx lobes subtriangular, 1–2.5 mm long, with external side and margins scabrous, with vinaceous hairs. Corolla infundibuliform, 2–4 mm long, white, yellow-green when dry; tube 2.3–2.8 mm long, externally glabrous, internally with a ring of moniliform hairs near the base; lobes triangular, 0.8–2 mm long, shorter than the tube, with 2–3 teeth at the apex outside, with a few scattered moniliform hairs at base inside. Stamens exserted, filaments dimorphic, inserted at the sinuses of the corolla lobes, papillate, the 2 longer filaments 0.5–1 mm long, the 2 shorter filaments 0.25–0.5 mm long; anthers oblong, 0.4–0.6 × 0.3–0.4 mm. Style exserted, 3–5 mm long, bifid, style branches 0.5–1 mm long, papillate; nectary disc bipartite. Capsules subsessile (pedicels 0.6–1 mm long), ovoid, 1.5–2 × 1.7–2 mm, glabrous, with 2 septicidally dehiscent valves. Seeds ovoid, 1.5–1.6 × 0.6–0.7 mm, dark brown; dorsal surface convex, ventral surface with a deep groove, covered by hyaline strophiole and some sparse raphids; testa reticulo-papillate, cells digitate, periclinal walls convex with a subcircular depression and a little excrescence at the apex, anticlinal walls curved or sinuous (Fig. 9 A–C).

Distribution:—*Borreria heteranthera* is endemic to Serra dos Carajás, an isolated mountain range on the eastern Amazon area, in Pará State, Brazil. It grows particularly at the Serra Norte and Sul from Parauapebas and Canaã dos Carajás municipalities.

Ecology and Phenology:—Growing in *campos rupestres* and gramineous flat fields on *canga*, and in shrubby vegetation with iron-rich rocks outcrops, on mountain summits, at 600–800 m elevation; flowering and fruiting from February to May. The vegetation of this area is characterized by evergreen, semideciduous, and deciduous forests, and by patches of saxicolous shrubby vegetation called *canga* (Secco & Mesquita 1983) or *campos rupestres* (i.e., rocky outcrops; Silva *et al.* 1996).

Conservation status:—According to the IUCN criteria (IUCN 2012) *Borreria heteranthera* should be classified as endangered [EN B2ab(ii, iii, iv)]. The extent of occurrence (EOO) is calculated to be 15.424 km², and the area of occupancy (AOO) is estimated at 20.000 km² (cell sized 2 km) in a fragmented area. The species is known from several localities, representing two locations from the northern of Pará State. The region where Serra dos Carjás is located is experiencing mining activity, especially linked to the exploitation of ferrous material, threatening the local natural vegetation.

Viana, L. M. Versieux, L. C. Garcia, V. T. Giorni, L. V. C. Silva & D. S. Silva 4094; C, I–L from A. J. Arruda, P. L. Viana, F. M. Santos, P. B. Mayer, T. J. Battituci & L. J. Arruda 909; D, E from A. J. Arruda, F. M. Santos, L. J. Arruda & T. J. Battituci 1099). Illustration by L. Simón.

Annual erect or rarely semi-prostrate herb, 7–30 cm tall; stems ramose at the base or simple with 4–5 opposite lateral branches, tetragon, slightly winged, glabrous with tiny papilla at the angle or densely hispid at the young branches, internodes 10–20(–40) mm long. Stipular sheaths subtriangular, 1–4 mm long, glabrous or hispid; setae 4–5, 1–4 mm long, hispid and colleters-tipped. Leaves opposite or sometimes pseudoverticillate (due to axillary brachiblasts), sessile or rarely pseudopetiolate; blades linear-lanceolate to lanceolate, 5–19(–30) × 1–7(–9) mm, attenuate at base, acute at apex, papery, glabrous, puberulous to pubescent above, densely pilose below, principally on secondary veins, margins revolute, scabrous. Inflorescences with 1 terminal and 4–5 axillary glomerules, on principal stems and opposite lateral branches, pauciflorous; bracts 4(–6), unequal, not sheathing, ovate-lanceolate, base subcordate,

the larger and external pair of bracts $6–10 \times 2–4$ mm, 2–4, the smaller internal bracts $4–8 \times 1–3$ mm long, absent in axillary glomerules. Flowers 4-merous, subsessile (pedicels 0.1–0.2 mm long). Hypanthium obconic, 0.75–0.8 mm long, glabrous, puberulous or with sparse hispid hairs. Calyx lobes lanceolate to triangular, 1–3 mm long, glabrous, scabrous or hispid, with hyaline apiculus, 0.5–0.65 mm long. Corolla infundibuliform, 2.25–2.5 mm long, white; tube 1–2 mm long, glabrous outside, with a ring of moniliform hairs at 1/3 from the base inside; lobes triangular, 0.5–1 mm long, with 2–3 teeth at the apex outside. Stamens exserted, with dimorphic filaments, the 2 longer filaments inserted at the sinuses of the corolla lobes, 0.3–0.5 mm long, the 2 shorter filaments inserted at the top of the corolla tube, 0.05–0.1 mm long, anthers oblong $0.35–0.3 \times 0.25–0.2$ mm. Style exserted, 1–2 mm long, bifid; style branches 0.45–0.8 mm long, stigmatic surface papillate; nectary disc bipartite. Capsules subsessile (pedicels 0.2–0.8 mm long), subglobose, $0.8–2 \times 0.9–1$ mm, hispid at the sepals, with 2 septicidally dehiscent valves. Seeds oblong, $0.6–0.8 \times 0.3–0.4$ mm, round at both ends, base acuminate, dark brown; dorsal surface convex, ventral surface flat with a broad groove covered by strophiole exceeding the apex of the seed with some raphids; testa surface papillate, cells digitate, periclinal wall convex with rounded ends, anticlinal walls sinuous (Fig. 9 D–F).

FIGURE 4. *Borreria heteranthera* E.L. Cabral & Sobrado. A. Habit. B. Detail of terminal glomerule. C. Flowers. Photographs by A. J. Arruda.

Distribution:—Central and northern Brazil, French Guiana, Guyana, Suriname and Venezuela; at 800–1000 m elevation.

Ecology and Phenology:—Open grasslands, savannas and rocky fields or granitic outcrops, occasionally along roadsides. Flowering and fruiting from November to July.

Remarks:—Schumann (1888) described *Borreria hispida* and cited two collections in Flora Brasiliensis: *Leprieur s.n.* from French Guiana, and *Spruce 663* from Pará, Brazil. The specimen collected by *Leprieur* could not be located in this study. *Spruce 663* at the Martius herbarium in Munich (M) is well-preserved and has at least 10 duplicates distributed in numerous herbaria. For this reason, we select *Spruce 663* at M as the lectotype of this taxon. Besides this,

we consider important to remark a controversial situation about the *Spruce* collection number cited in the protologue of the species. The label of the M specimen has the number “663” handwritten with a different calligraphy (author unknown) from the original dates. Also, the label has the signature and the annotation “K. Schum.!” . This proves that Schumann saw this specimen, and cited this number in the species protologue. However, not all the available specimens of *Spruce* collected in “*Prope Santarem, Pará, Brazil, April of 1950*” has the same number written in its labels (i.e. JSTOR images from FI, K, MPU, S, and TCD herbaria). Also, the BM and NY specimens have labels annotated with this different calligraphy. Taking into account this handwritten annotation from all specimens analyzed, we think that this number does not correspond to Spruce’s collection number. However, we preferred to maintain 663 as Spruce’s collection number because its extensive use in the literature.

Conservation status:—According to the area of occupancy estimated (AOO: 152,000 km²; cell size 2 km) and following the IUCN criteria (2012), *Borreria hispida* should be considered as least concern. This is a widespread and well-collected species in several locations from open grasslands and granitic outcrops of the Guianas, Brazil, and Venezuela. The extent of occurrence (EOO) is calculated to be 4,836,460.459 km².

Borreria semiamplexicaule E.L. Cabral, Bonpandia 9: 37. 1996. *Spermacoce semiamplexicaule* (E.L. Cabral) Delporte, J. Bot. Res. Inst. Texas 1(2): 1028. 2007. Type:—BRAZIL, Pará, 25 km NW of camp at Serra Norte, approx. 5°54' S, 50°27' W, 13 December 1981, D. Daly, R. Callejas, M. G. da Silva, E. Taylor, C. Rosario & M. dos Santos 1993 (holotype: NY!; isotype: CTES!). (Figs. 1 G–H, 2 C, 6 A–M, 7 A–F, 9 G–I).

Annual herb, erect, 15–50 cm tall; stems simple or with opposite lateral branches starting from the base, subtetragonal, slightly winged, glabrous, internodes 3–8 cm long. Stipular sheaths 2–4 mm long, puberulous at the upper third; setae 4–6, 0.8–3 mm long; stipular sheath from the terminal glomerule with 3–4 setae. Leaves opposites, sessile; blades elliptic to linear, 10–40 × 2–12 mm, attenuate at base, acute at apex, membranaceous, margin with rough papillae, midrib conspicuous on the lower surface, secondary veins less evident. Inflorescences with 1 terminal and

2–6 axillary glomerules, pauciflorous; bracts 4–6, unequal, sub-sheathing to sheathing, base cordate to auriculate, the 2 larger external bracts $8–27 \times 2–3.5$ mm, the 2–4 smaller internal bracts $4–8 \times 2–3$ mm. Flowers 4-merous, subsessile (pedicels 0.35 mm long). Hypanthium obconic, 1.12–1.33 mm long, glabrous. Calyx lobes triangular, 1–3 mm long, margins with rough papillae or with red scabrous hairs. Corolla infundibuliform, 4–4.5 mm long, pale blue, rare white; tube 3.5–4.4 mm long, glabrous outside, with a ring of moniliform hairs near the base inside; lobes triangular, 1.2–1.4 mm long, externally with 2–3 tooth on the apex, with sparse moniliform hairs inside. Stamens exserted, filaments dimorphic, inserted at the sinuses of the corolla lobes, the 2 longer stamens with filaments 0.82–1 mm long, the 2 shorter stamens with sessile anthers, these oblong, 1–1.2 \times 0.23–0.35 mm. Style exserted, 3–4 mm long, stigma bifid, stigmatic branches 0.3–0.8 mm long, papillate; nectary disc bipartite. Capsules subsessile (pedicels 0.34–0.44 mm long), ovoid, 2.2–2.8 \times 2–2.7 mm, glabrous, with 2 septicidally dehiscent valves. Seeds ovoid, 1.5–2 \times 0.7–0.85 mm, blackish to dark brown; dorsal surface convex, ventral surface with a groove covered by a hyaline strophiole; testa surface reticulo-papillate, cells digitate. The cells have warty irregular projections with a subcircular depression at the apex (Fig. 9 G–I).

Distribution:—In the states of Pará, Goiás, Tocantins, and Mato Grosso, Brazil; at 200–800 m elevation.

Ecology and Phenology:—Flooded grassy fields, *campos rupestres* on ferrous rocky outcrop, in transitions between low forests to ombrophilous dense forest, near water courses, and also on lateritic soils. Always associated with marsh and wetlands. Flowering and fruiting from February to (probably) June.

Remarks:—This species was originally known from Pará and was recently reported by Delprate (2010) to occur in northern of Tocantins, Brazil. The specimen from Mato Grosso is the first record of this species for this state.

Conservation status:—The extent of occurrence (EOO) is calculated to be 368,675.3 km², and the area of occupancy (AOO) is estimated at 68.000 km² (cell size 2 km). Therefore, following IUCN red list categories and criteria (IUCN 2012), *Borreria semiamplexicaule* should be regarded as endangered [EN B2ab(ii, iii, iv)]. The planned mining activities, mainly in the area of Serra dos Carajás (Pará), are the main threat for the species. Moreover, is important to mention that the excessive farming activity in all other locations is also considering a threat for the species. This is presumed due to the soil quality that enables such activities.

Additional specimens examined:—**BRASIL. Mato Grosso:** Alta Floresta, 9°00' S, 55°00' W, 246 m, 27 January 2007, D. Sasaki, C. P. Vicenti, L. M. Paz & J. H. Annual herb, 10–20 cm tall; stems creeping or occasionally erect, 30–60 cm long, 3–5 opposite lateral branches, subquadrangular to tetragonal, winged, glabrous or sometimes hispid at the angles of young branches; internodes 5–9 cm long. Stipular sheaths triangular, 1.25–3 mm long, hispid to villous; setae 3–4, 1–4 mm long, villous, the central ones longer, colleters-tipped. Leaves opposite, pseudo-petiolate; blades ovate, 25–70 × 8–20 mm, attenuate at base, acute at apex, chartaceous, margins scabrous, pubescent above and underneath. Inflorescences with 1 terminal and 3–4 axillary glomerules, on principal stems and on opposite lateral branches; glomerules multi-flowered; bracts 6–8, unequal, sheathing and covering all the glomerules, pseudo-petiolate, foliaceous pubescent, the 4 larger external bracts, ovate, 11–16 × 11–14.5 mm; the 2(–4) smaller internal bracts suborbicular or elliptic, 8–12 × 5–11 mm. Flowers 4-merous, subsessile (pedicels 0.5–0.6 mm long). Hypanthium narrowly ovate, 1.5–2 mm long, with sparse hispid hairs. Calyx lobes triangular, 0.8–1.2 mm long, united at base in a short tube, 0.55–0.7 mm long, hispid. Corolla infundibuliform, 3.75–4 mm long, pale blue-purple; tube 2.2–3 mm long, glabrous outside, with a ring of moniliform hairs at lower third inside, lobes triangular, 0.7–1 mm long, with some papillae near the tips outside, with sparse hairs near the anther insertions inside. Stamens 4, unequal, the 2 longer ones slightly exserted, inserted at the corolla lobes sinuses, filaments 0.12–0.2 mm long, the 2 shorter ones included, inserted at 0.86–1 mm below the sinuses of the corolla lobes, anthers subsessile, oblong 0.5–0.6 × 0.44 mm. Style exserted, 3.35 mm long, stigma bifid, stigmatic branches 1.07 mm long, stigmatic surface papillate; nectary disc bipartite. Capsules subsessile (pedicels 0.6–1.5 mm long), oblong, 3.6 × 1.8–2 mm, hispid at the sepals, with 2 septicidally dehiscent valves. Seeds oblong-ellipsoid, 2.4–3.2 × 0.9–1.35 mm, round at both ends, brown; dorsal surface convex, ventral surface slightly flat with a longitudinal narrow groove forming a straight line from one end to the other; testa surface rugulose-papillate; cells digitate, periclinal walls convex and slightly striate at the round end, anticlinal walls curved or sinuous (Fig. 9 J–L).

Distribution:—Only known from French Guiana and Suriname; at 200–400 m elevation.

Ecology and Phenology:—Edges of shrubby vegetation on rocks, at the edges and on top of granitic inselbergs. Flowering and fruiting from July to December.

Conservation status:—According to the extent of occurrence calculated (EOO: 25,091.008 km²) this species could be considered as a threatened species. However, the area of occupancy (AOO) is estimated at 28.000 km² (cell sized 2 km) in a severely fragmented area; besides, the species is known from nine collections from French Guiana. Therefore, following IUCN criteria (IUCN 2012), the species can be referred to as an endangered (EN B2ab(ii, iii, iv)).

Discussion

The new species *Borreria heteranthera* and the other three species presented in this study display a peculiar staminal arrangement. This phenomenon represents an unusual and so far the only reported case in Rubiaceae showing an intrafloral variation of insertion/length of stamens in homostylous flowers. As we explained above, this feature, first described by Aublet (1775: 60), was little used in the taxonomic descriptions of this species group. For this reason, we propose the staminal organization as a diagnostic feature in the Amazonian species of *Borreria* subsection *Latifoliae*. Indeed, we consider this feature very important, because the genus *Borreria* is entirely homostylous. An analogous case occurs in the Neotropical genus *Ferdinandusa* Pohl (1831: 8). The species of this genus as same *Borreria heteranthera* and *B. semiamplexicaule* display an intrafloral variation of the filaments length. *Ferdinandusa* is a homostylous genus and has inserted or exserted stamens, with subequal or filaments with variable length (Delprete 2010, 2012). However, this genus does not present a staminal arrangement in pairs similar as the species of *Borreria* cited, and also has protandrous flowers. Other similar case occurs in the endemic Madagascan genus *Amphistemon* Groeninckx (2010:

450). This genus is the only in Spermacoceae with anthers positioned at two levels in the corolla tube. However, it differs from the four species presented here by having heterostylous flowers (Groeninckx *et al.* 2010).

Detail of the rugulate-papillate testa and digitate cells. Scale bar 200 µm.

Borreria subsection *Latifoliae* consists of ca. 12 South American species with the inclusion of *Borreria heterantha* and *B. xanthophylla*. The four species here analyzed present a relatively uniform seed morphology. The seeds are brown, ovoid (*Borreria heterantha* and *B. semiamplexicaule*) or oblong and round at both ends (*B. hispida* and *B. xanthophylla*), and similar sizes (1.5–2.4 x 0.6–1.35). Except in *B. hispida*, which has the smallest seeds (0.6–0.8 x 0.3–0.4 mm) in the group. The ventral surface is flat and presents a ± deep groove, covered by a hyaline strophiole and raphids. In *B. hispida*, the strophiole exceeds the apex of the seeds. The testa surface is reticulo-papillate (*B. heterantha* and *B. semiamplexicaule*), rugulose-papillate (*B. xanthophylla*), or simply papillate (*B. hispida*). According to these observations, we concluded that the seed morphology is a uniform feature for this species group. Although this is not an interspecific diagnostic feature, it can be used to characterize these species. The pollen morphology is also uniform among them. The grains are zonocolpate (8–11), oblate-spheroidal to prolate-spheroidal (P/E= 0.84–1.06), medium-sized (P= 31–45 µm; E= 33–45 µm), and with a circular polar outline. The colpi are medium-sized (LC/P= (23–)26–38) and slit-like. The endoaperture is a ring-shaped endocingulum lying in the equatorial plane ranging (4–)7–10 µm long at the colpus zone. In this area, the endocingulum appears as a round end at SEM. However, broken grains observed at SEM confirmed that is a continuous endoaperture, with or without mesocolpium extensions. The tectum is uniformly spinulate and present irregular perforations ranging 0.16–0.4 µm in diameter. The nanospines are 0.25–0.5 µm long. The inner nexine surface is finely granular and may present narrow and superficial endocracks or broad and deep irregular ones. The above features correspond with the pollen type 2 described by Pire (1996) and Dessein *et al.* (2002). This pollen type was originally characterized by its 8–9-colporate and medium-sized grains with medium colpi, tectum with ± large perforations, and uniformly spinulate. Pire (1996) linked this pollen type to some species of *Borreria* subsection *Latifoliae* (*Borreria balansae* Standley (1931: 389), *B. latifolia* (Aublet 1775: 55–57) Schumann (1888: 61), *B. nana* Standley, *B. poaya* (Saint Hilaire 1824: XII) Candolle (1830: 549), and *B. wurdackii* Steyermark (1972: 812). However, we found some differences between the species cited above (Sobrado & Cabral, in press), the four species treated in the present study, and the Pire (1996) and Dessein *et al.* (2002) proposals. The inner surface nexine and the endocingulum analyzed allow us to re-describe the pollen type 2 *sensu* Pire (1996). Moreover, *Borreria hispida* and *B. semiamplexicaule* were classified initially as type 3-subtype 3b (Pire 1996). This type is recognized by its 6–9(–10–12)-orthocolporate or loxocolporate grains, with short and narrow colpi, oblate-spheroidal or less frequent protale-spheroidal and suboblate, with small or medium size, and perforate tectum, uniformly spinulate. According to the arrangement and length of the apertures and the presence of an endocingulum we transfer these two species from the pollen type 3-b to the type 2 pollen group.

Acknowledgements

We are grateful to Alexandre Salino (BHCB) for loans of herbarium specimens, and to Roxali Bijmoer (L, Collections Manager) for digital images of the *Borreria xanthophylla* type. Also, we thank Roberto M. Salas for the information obtained from the M herbarium, and Laila M. Miguel for the comments suggestions. We also thank to Laura Simón for preparing the line drawings and to Pedro L. Viana and André J. Arruda for the photographs. The first author thanks to Consejo Nacional de Investigaciones Científicas y Tecnológicas (CONICET), for the grants awarded that support this work. We thanks to two anonymous reviewers and the editor also for suggestions on the manuscript.
